

Land surface parameter sensitivity of tropical forest hydrological cycle in a perturbed parameter ensemble

Kate Halladay and Peter Good (Met Office Hadley Centre)

JULES meeting, Edinburgh, 22nd July 2019

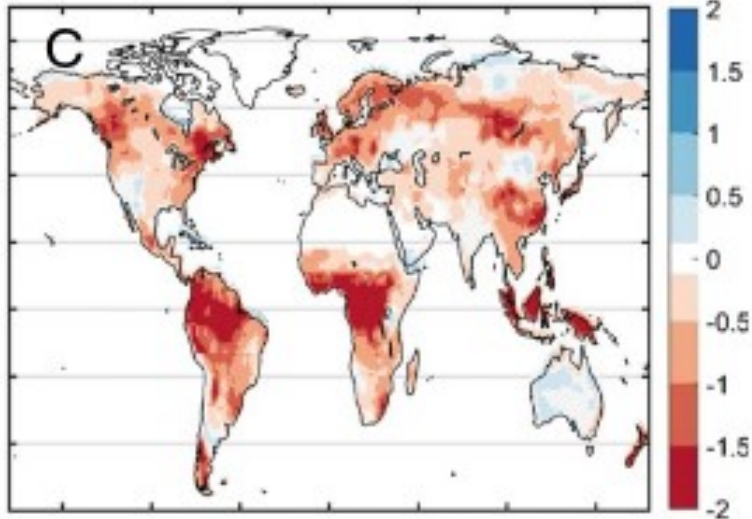

kate.halladay@metoffice.gov.uk

One of the responses of vegetation to increased CO₂ :
→ **stomatal closure** → **reduced transpiration**

This is known as “**physiological forcing**”

ET response to 4xCO₂ in CMIP5 models

Lemordant *et al* (2018)

Mean precip response in HadGEM2-ES

Mean precip response in CCSM4

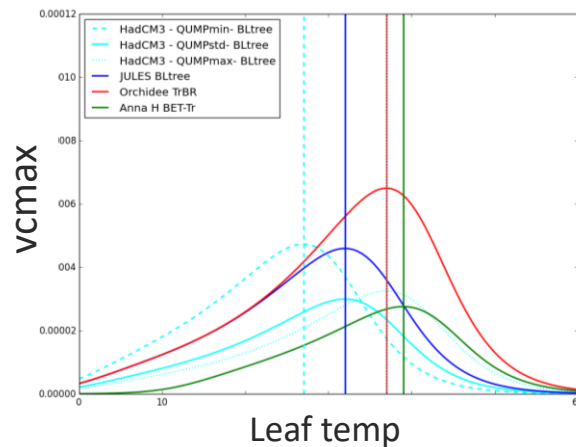

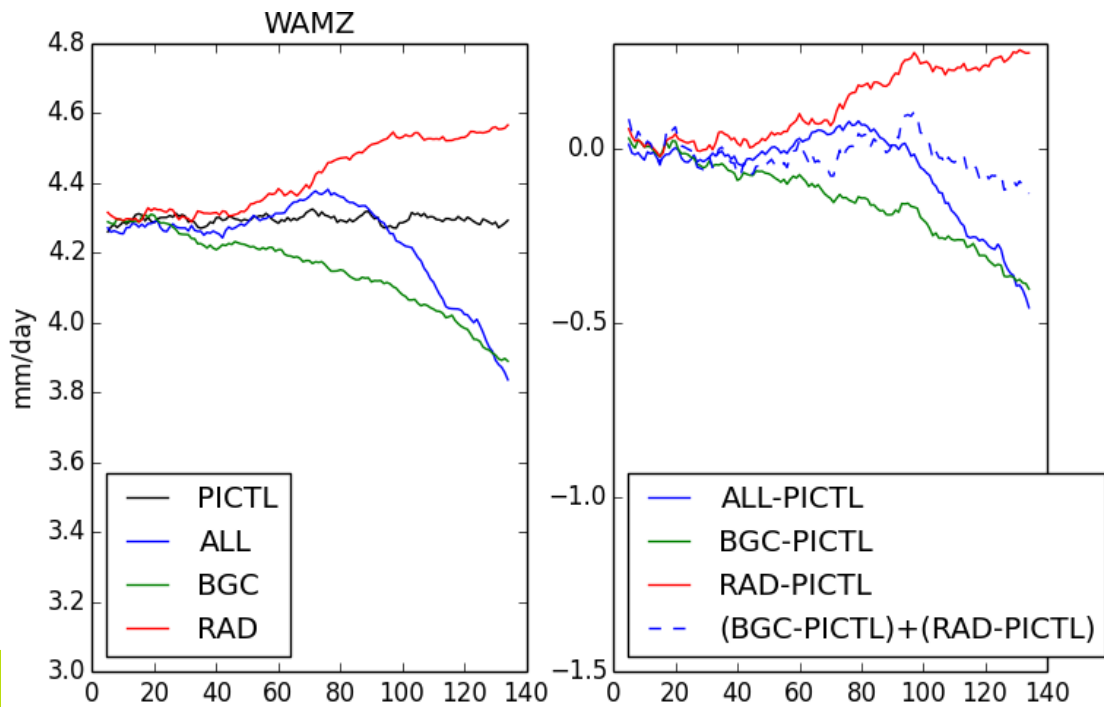

Chadwick *et al* (2017)

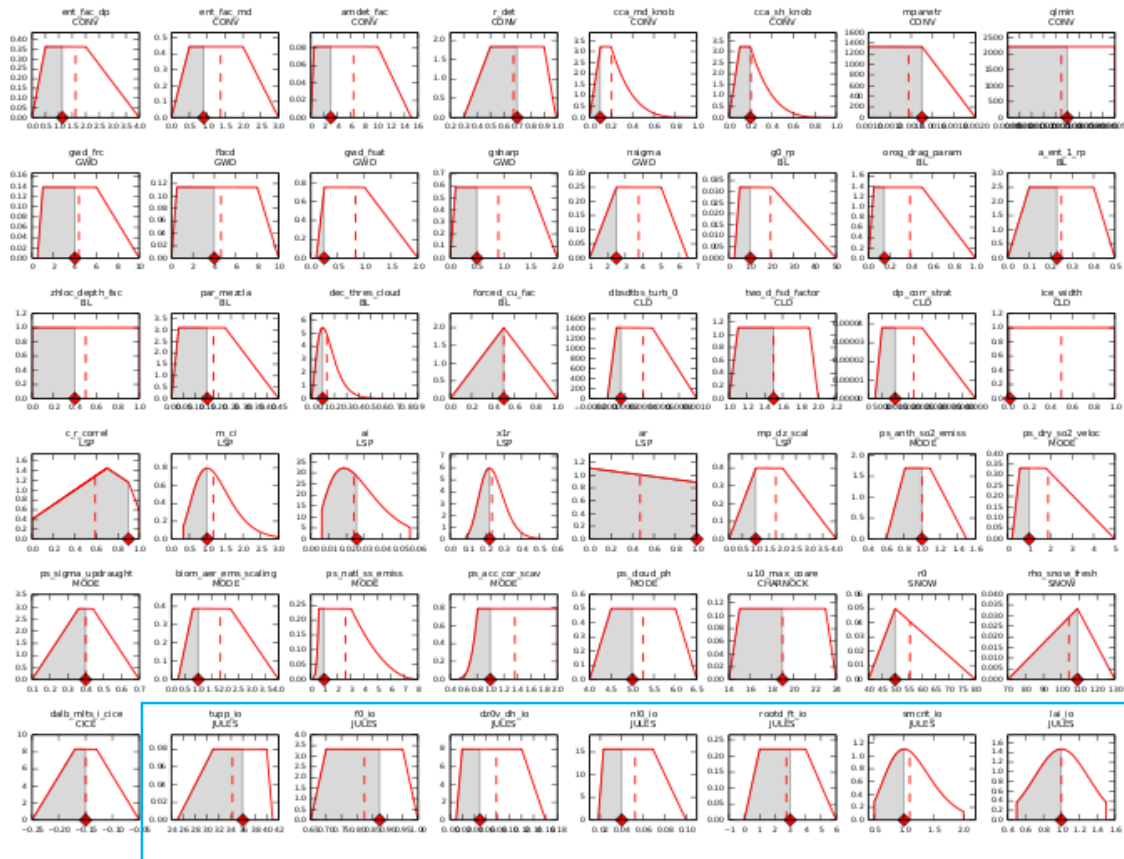

'ALL' ($1pcCO_2$) : all model schemes exposed to the CO_2 rise

'BGC' (*esmFixClim1*) : **physiological** forcing i.e. only vegetation scheme exposed to CO_2 rise

'RAD' (*esmFdbk1*) : **radiative** forcing i.e. only radiation scheme exposed to CO_2 rise

Upper value about 4K above T_{opt} the optimal Temperature for photosynthesis ($t_{upp.io}$)	T_{opt} determines the turn-over point for temperature, above which further increases in temperature will drive a decline in photosynthesis.	In tropical and sub-tropical regions the optimal temperature would be expected to have the biggest impact on plant functioning, with low values for this parameter leading to greater temperature dependence of photosynthesis.
Maximum ratio of internal to external CO_2 ($f_{0.io}$)	Controls the gradient of CO_2 between plant stomata and the ambient air.	
Top leaf Nitrogen concentration in kg N kg C ($nl_{0.io}$)	Defines the top leaf ratio of nitrogen to carbon. Plant photosynthesis (V_{cmax}) is defined in the model to be proportional to the Leaf Nitrogen. concentration	Higher ratios are associated with higher photosynthesis.
Root depth ($rootd_{ft.io}$)	Controls the depth (in model soil levels) that soil moisture is available.	Larger values equate to deeper depths in the soil, and subsequently greater resilience to short timescale droughts.
Scaling factor for Critical and Saturation levels for Soil Moisture towards Wilt level (psm)	This pair of parameters control the critical and saturated volumetric soil moisture thresholds. The critical threshold controls the level above which evapo-transpiration is no longer soil moisture dependent.	Higher values lead to larger soil moisture regimes where soil moisture limits this evapo-transpiration, with its consequent implications for moisture and surface energy fluxes.

- 52 parameters varied across 2915 experiments
- All parameters varied simultaneously

- Land surface parameter uncertainty is clearly significant if we believe that the chosen ranges of values are realistic!
- There are spatial and seasonal variations in sensitivity.
- Greatest parameter sensitivity occurs in tropics, especially in tropical forests (probably because transpiration is high).

- Further work required to understand the spatial and seasonal variability in parameter sensitivity.
- Can we constrain parameter value based on observations? Other studies suggest structural error may prevent this.
- How does parameter uncertainty change with higher temperatures?

mm/day

Spatial variability in parameter sensitivity

- Darker colours indicate steeper gradient (greater sensitivity to change in parameter)
- Red = negative slope
- Blue = positive slope

Spatial variability in parameter sensitivity (%)
