Making the case for explicitly modelling microtopography in permafrost landscapes

Noah Smith (University of Exeter) + Sarah Chadburn, Eleanor Burke & more!

Why model microtopography?

Methane & carbon fluxes!

The permafrost landscape is highly heterogeneous
→ Leading to feedbacks exacerbating permafrost thaw
→ And also changing carbon fluxes

Making wetlands wet

- Surface ponding
- Correction for saturation numerics (l_soilsatupdown)
- Evaporation correction for very wet soil Sarah Chadburn
- qbase is off (for the moment)

l_soilsatup = .true.

Final slide

- Microtopography has ~ 10% difference to methane fluxes vs std JULES
- However change in methane emissions is driven by the change in wetland area and permafrost extent
- ...which is driven in part by microtopographic effects (e.g. thermokarst).
- This approach may also better enable modelling soil carbon history and labile carbon
