

# Projected impacts of climate change on large-scale water resources at 1.5°C, 2°C and 4°C global warming

Richard Betts, Lamprini Papadamitriou, Aris Koutroulis, Pierre Friedlingstein, Catherine Morfopoulos, Klaus Wyser

**Met Office**

**Context:** the United Nations Paris Agreement aims to limit global warming to “well below” 2°C relative to pre-industrial – “pursuing efforts” to limit to 1.5°C

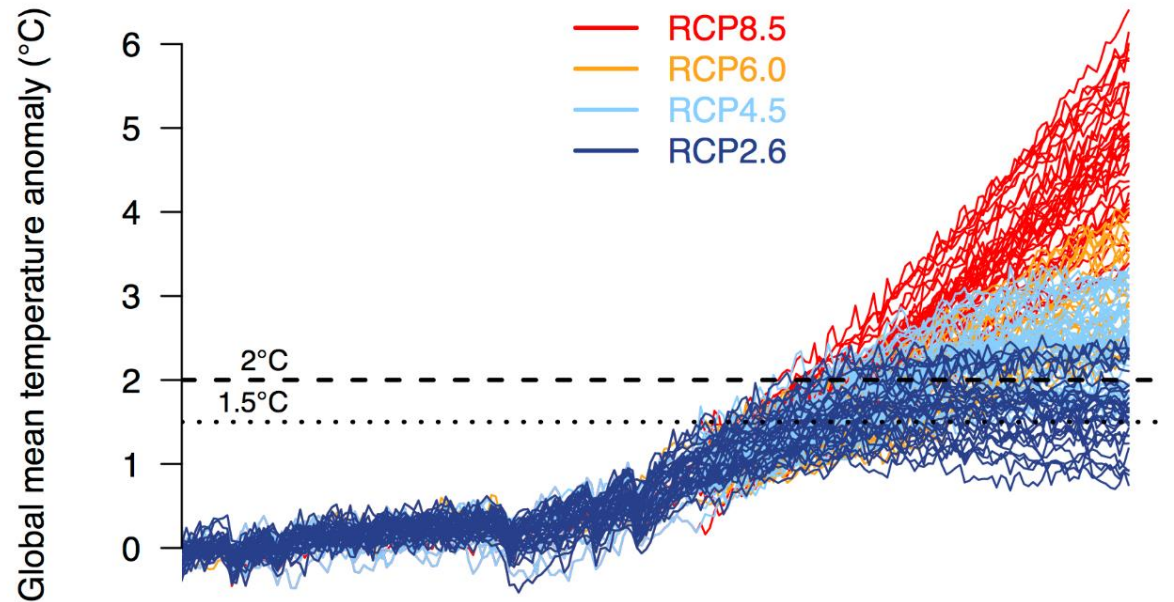

**Key questions:**

1. What will be the impacts at 2°C?
2. How much of these can we avoid if we achieve 1.5°C?
3. What will be the consequences of missing these targets?  
Eg. what happens at 4°C?

Address this here for **freshwater resources**, using climate projections to drive **JULES** to simulate changes in **runoff**

Global mean temperature projected by CMIP5 multi-model ensemble

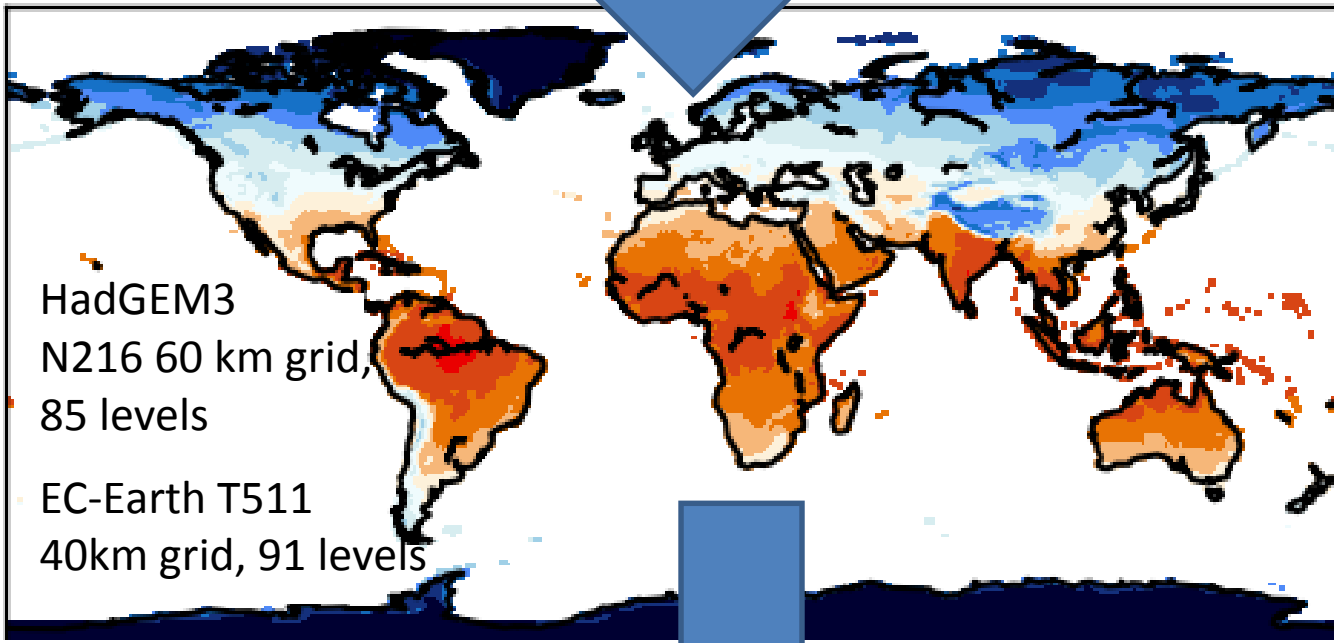

CO<sub>2</sub> concentrations in RCPs (Representative Concentration Pathways)

# Here focus on RCP8.5 scenario

Existing CMIP5 projections with RCP8.5: GHGS, sea surface temperatures, sea ice

New higher-resolution models than in CMIP5 (atmosphere only)

Various impacts sectors: use JULES for water resources

## JULES setup

“JULES-W1” configuration – as used in Water sector of ISIMIP (Inter-Sectoral Impacts Model Intercomparison Project) Phase 2 (Papadimitriou *et al.*, 2016; 2017)

Global domain, 0.5° resolution

Vegetation: 5PFTs prescribed at present-day state

Plant physiology responds to changing CO<sub>2</sub> concentrations

(ie: stomatal closure affects transpiration, but no change in leaf area index or vegetation distribution)

No irrigation, crops or glaciers

Driving data from HELIX climate projections bias-corrected with observations (Watch Forcing Data Era-Interim) – as in ISIMIP2

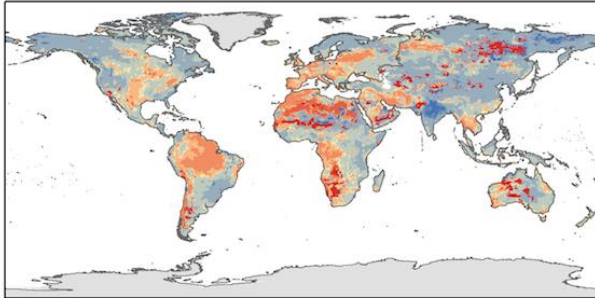

## **Key questions arising from the experimental design:**

What is the role of the different SST and sea ice change patterns for regional climate changes?

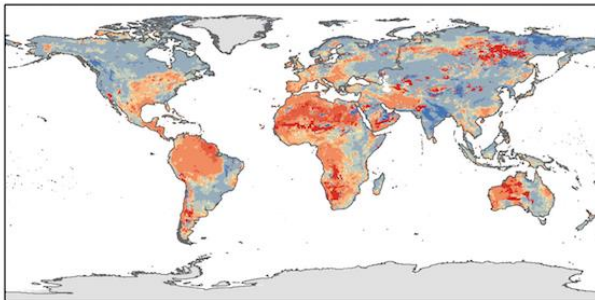

Do the two atmosphere models respond differently?

# Projected changes in annual mean runoff at 2°C global warming: JULES driven by HadGEM3 atmosphere with patterns of SST and sea ice change from 6 CMIP5 models

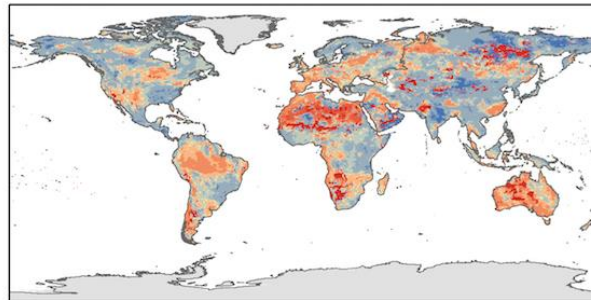

Ensemble Mean

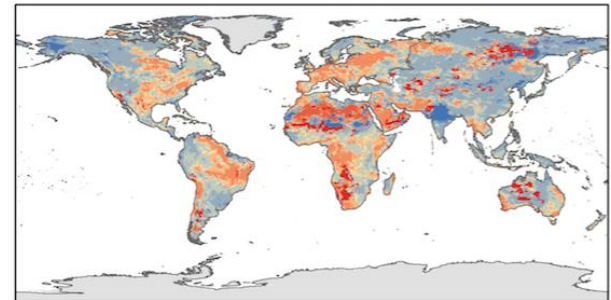

IPSL-CM5A-LR

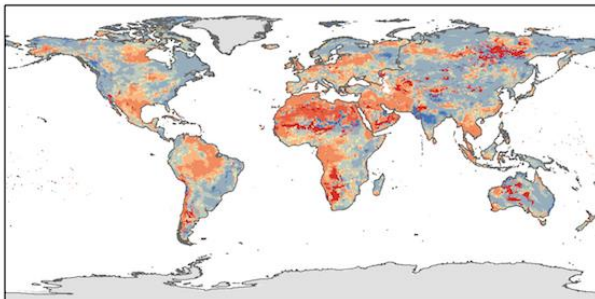

GFDL-ESM2M

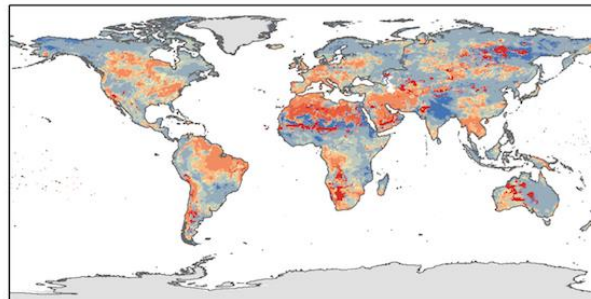

HadGEM2-ES

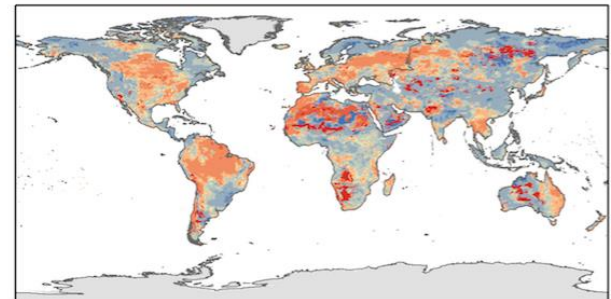

IPSL-CM5A-MR

MIROC-ESM-CHEM

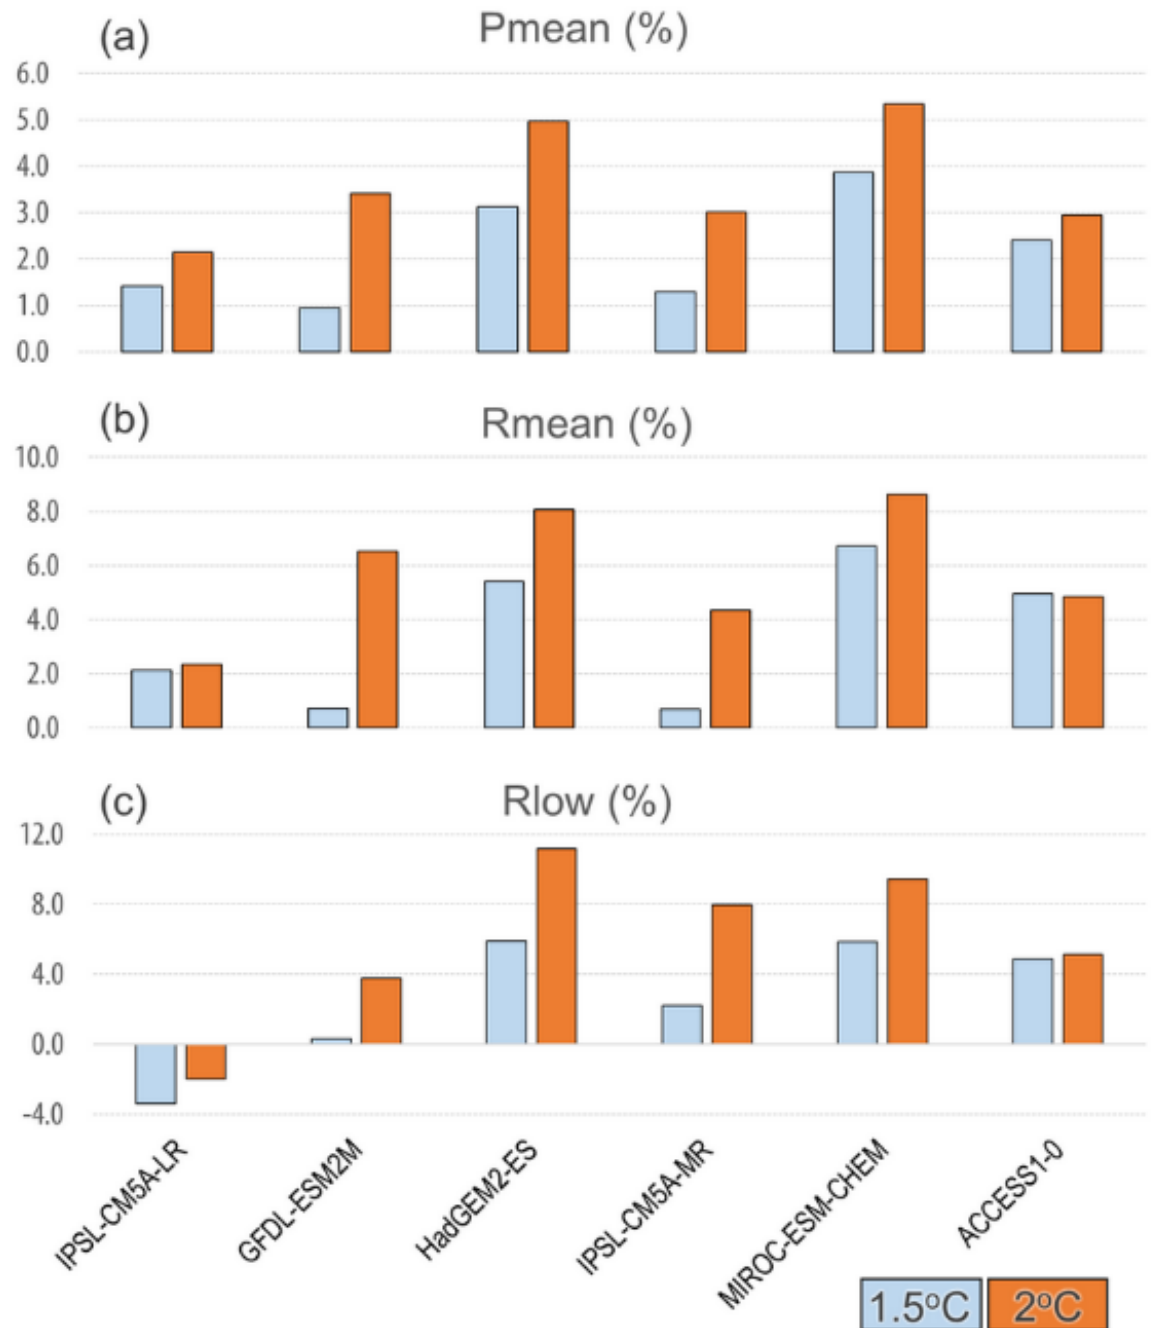

ACCESS1-0

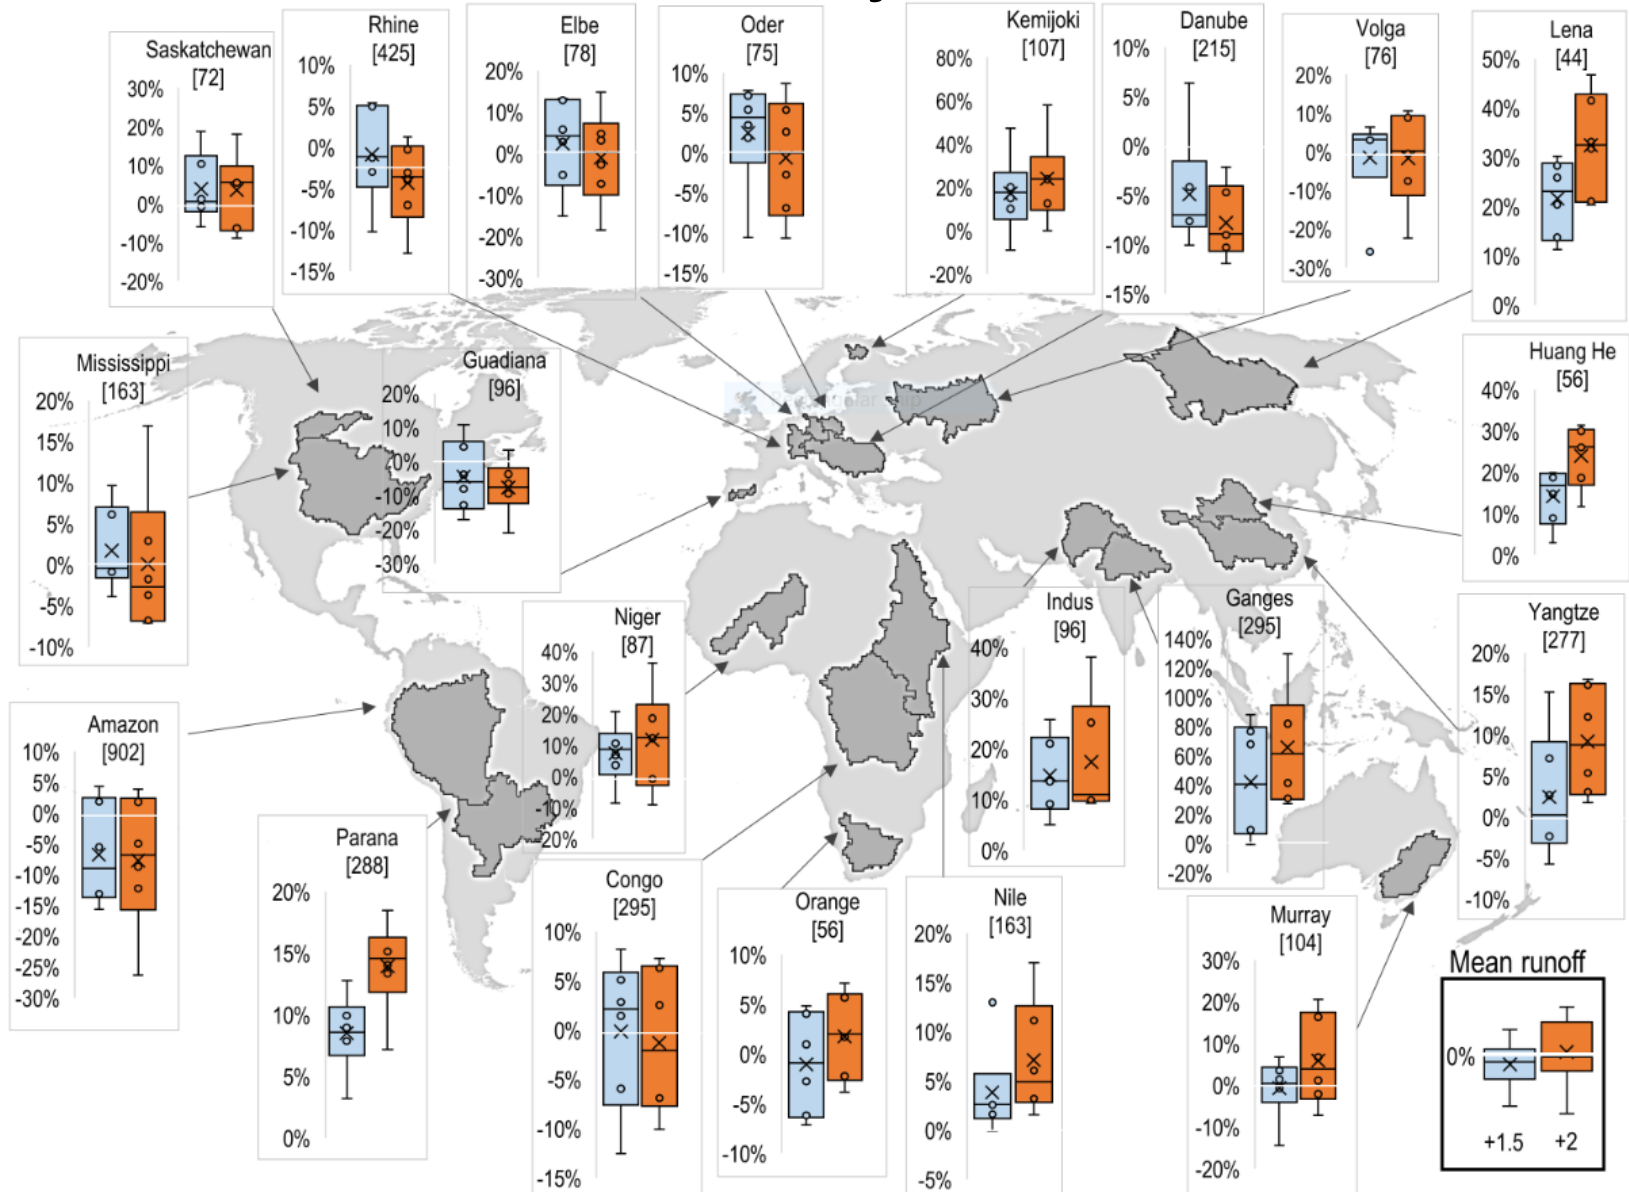

Global mean % changes in precipitation (P), annual mean runoff (Rmean) and 10<sup>th</sup> %ile runoff (Rlow) at 1.5°C and 2°C global warming

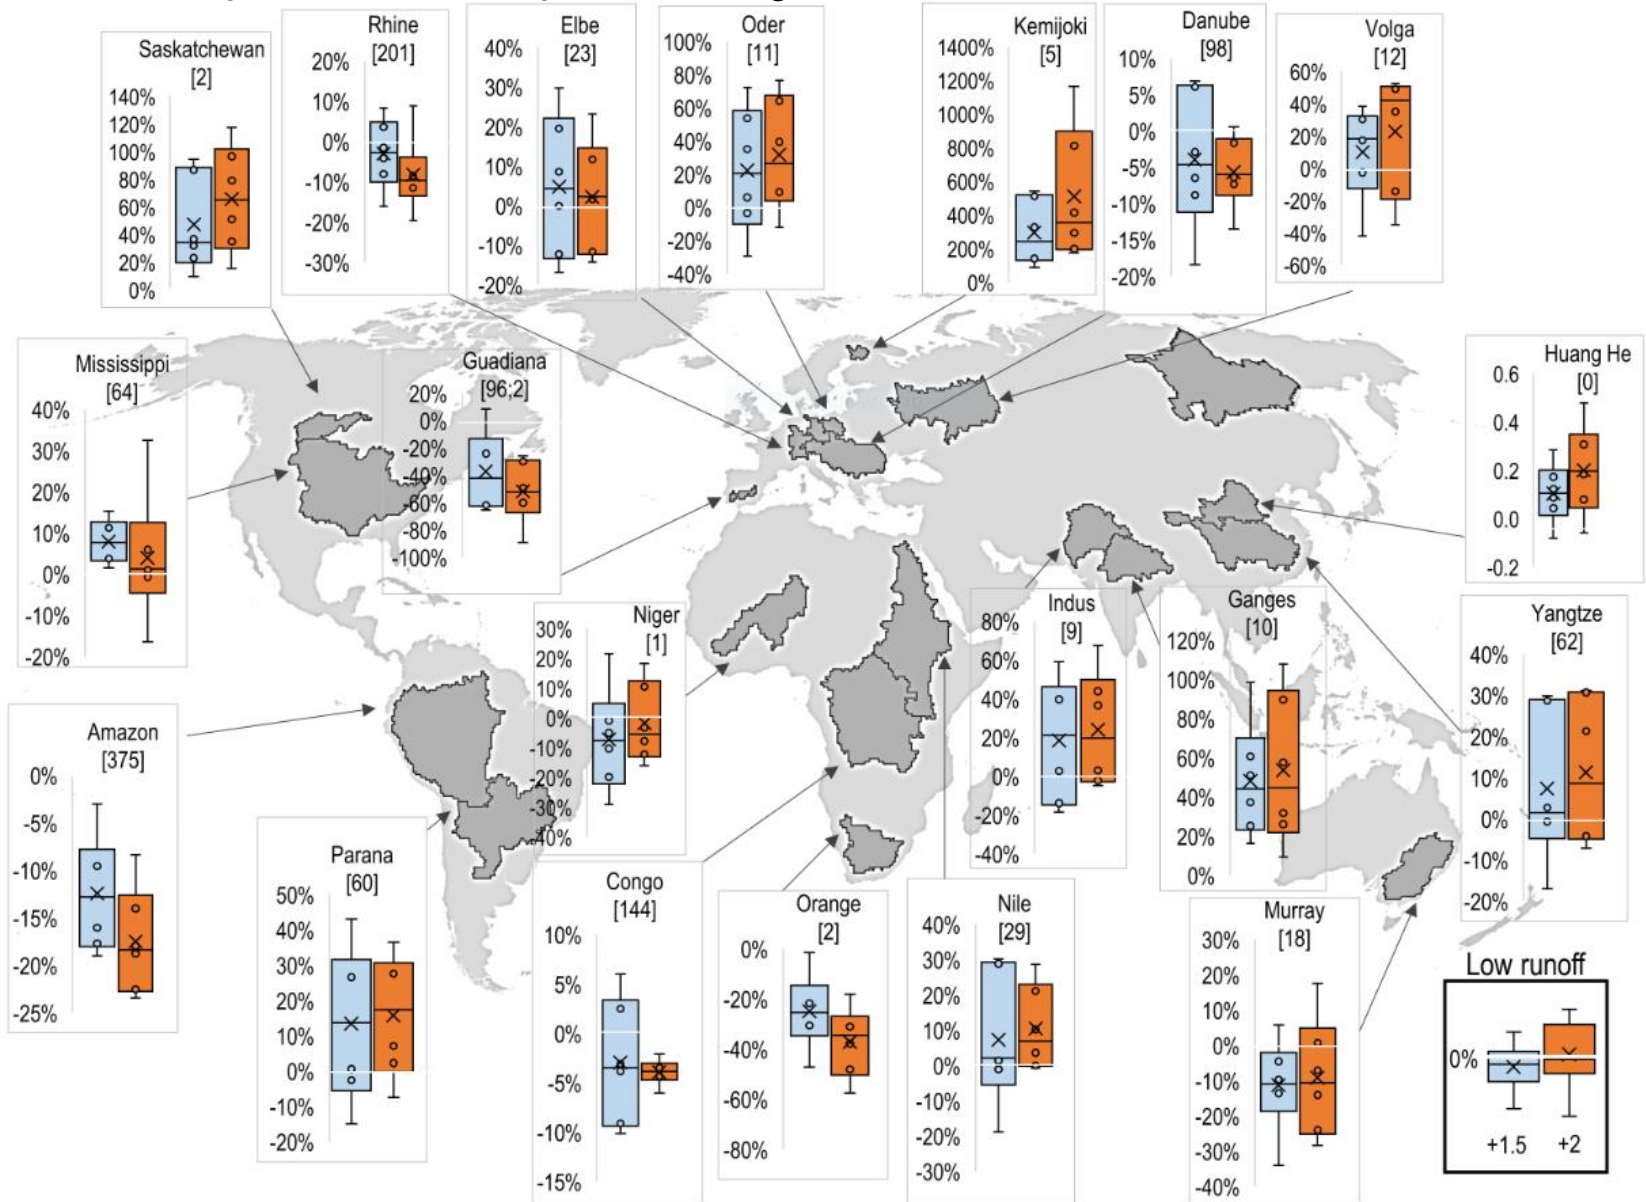

JULES driven by HadGEM3 atmosphere model with SSTs and sea ice from 6 CMIP5 climate models

# Ranges of projected changes in annual mean runoff in major river basins

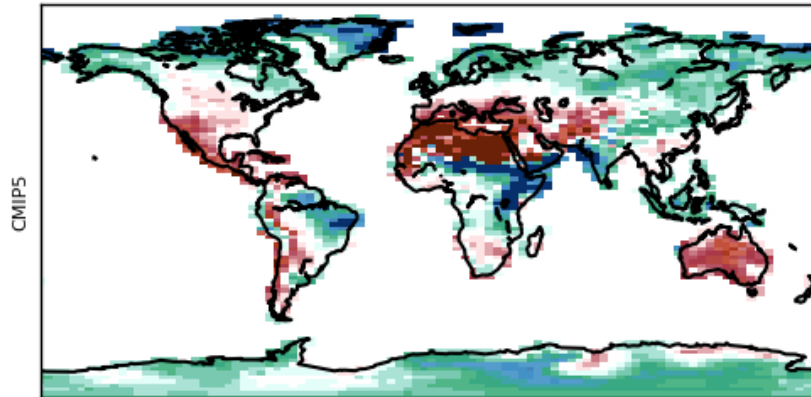

# Ranges of projected changes in low runoff (10<sup>th</sup> %ile) in major river basins

Does the choice of atmosphere model make a difference to regional responses to SSTs?

Change in annual mean precipitation at 4°C global warming

IPSL-CM5A-LR

Original IPSL model in CMIP5

EC-Earth T511 with IPSL SSTs

HadGEM3-GA3 N216 with IPSL SSTs

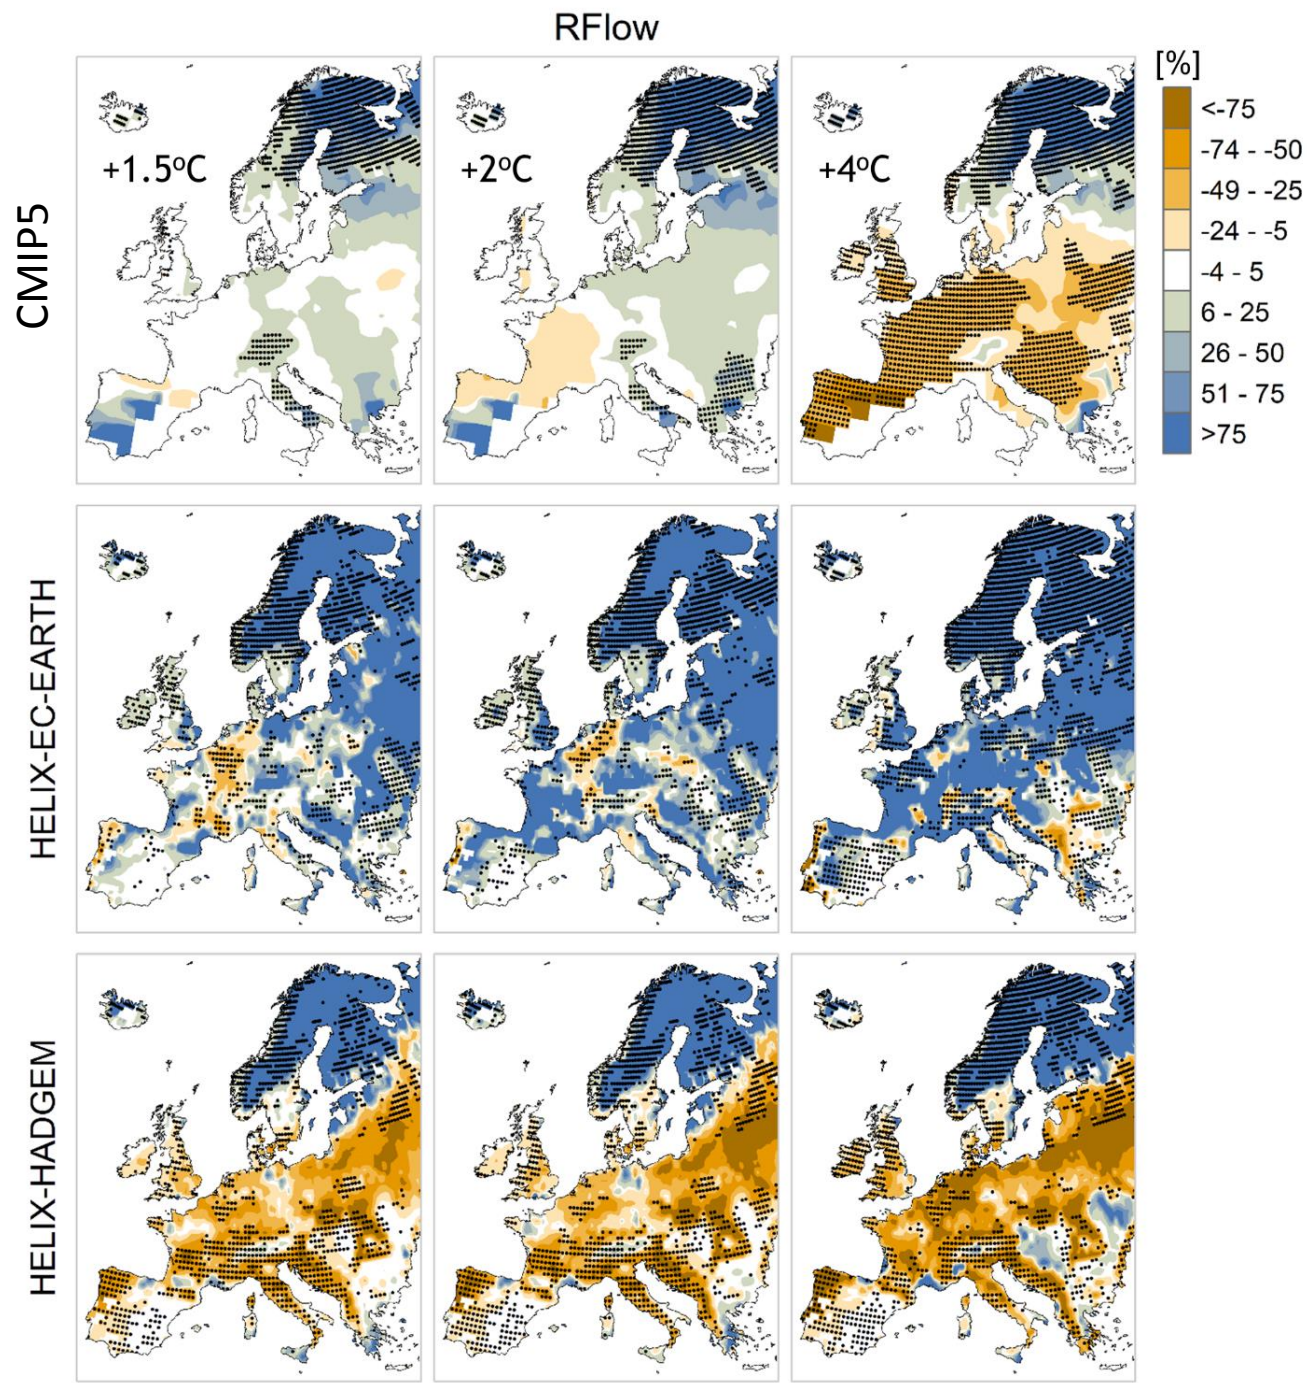

Effect of different atmosphere models with same SSTs

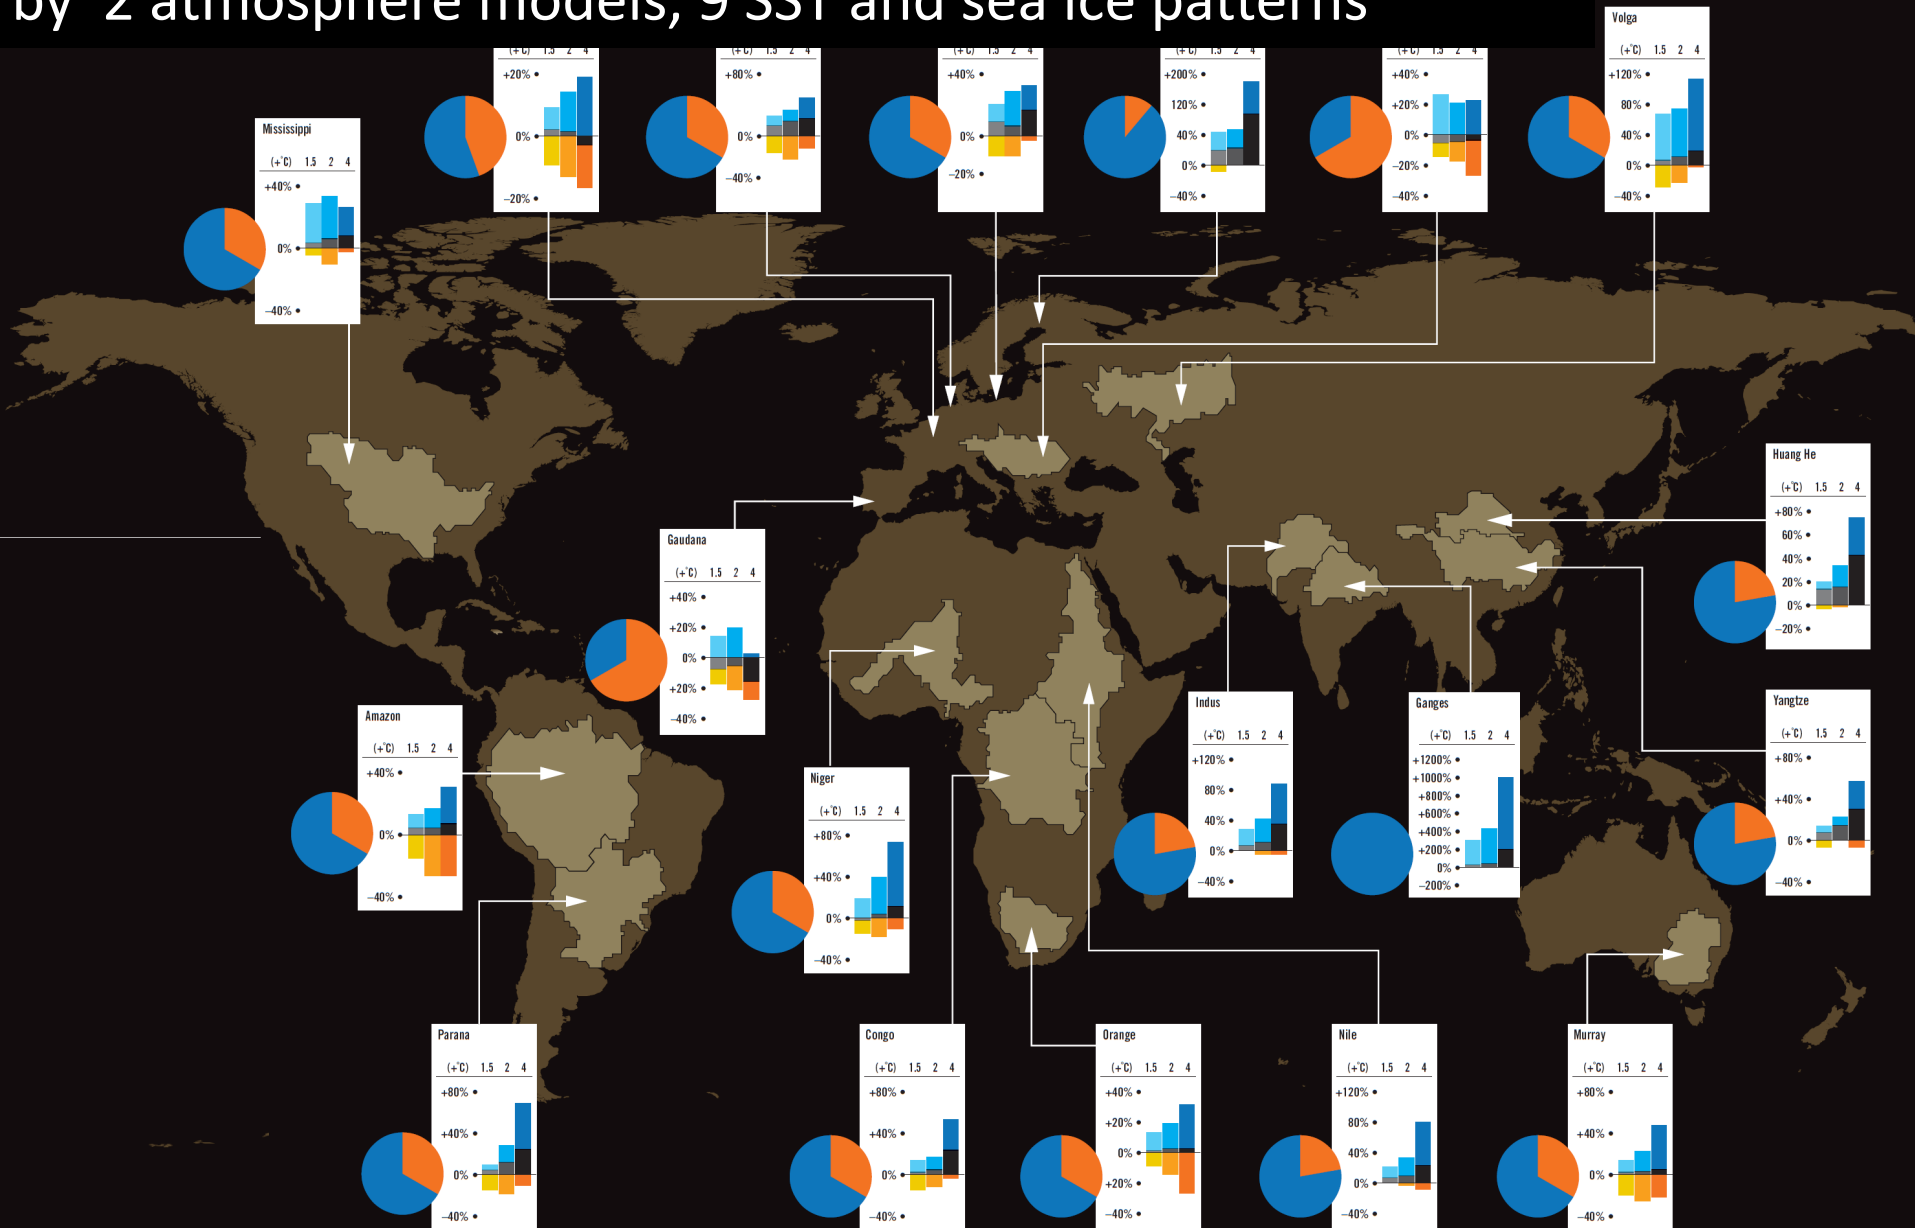

Hydrological drought (10<sup>th</sup> %ile low flows) simulated by JULES

Common SST driving models

- IPSL-CM5A-LR
- GFDL-ESM2M
- HadGEM2-ES

# River flow changes projected at 1.5°C, 2°C, 4°C: JULES driven by 2 atmosphere models, 9 SST and sea ice patterns

## What does this mean for people?

Use 3 different scenarios of population and economic state from the Shared Socioeconomic Pathways (SSPs)

SSP3 “high challenge to adaptation”

SSP2 “medium challenge to adaptation”

SSP5 “high challenge to adaptation”

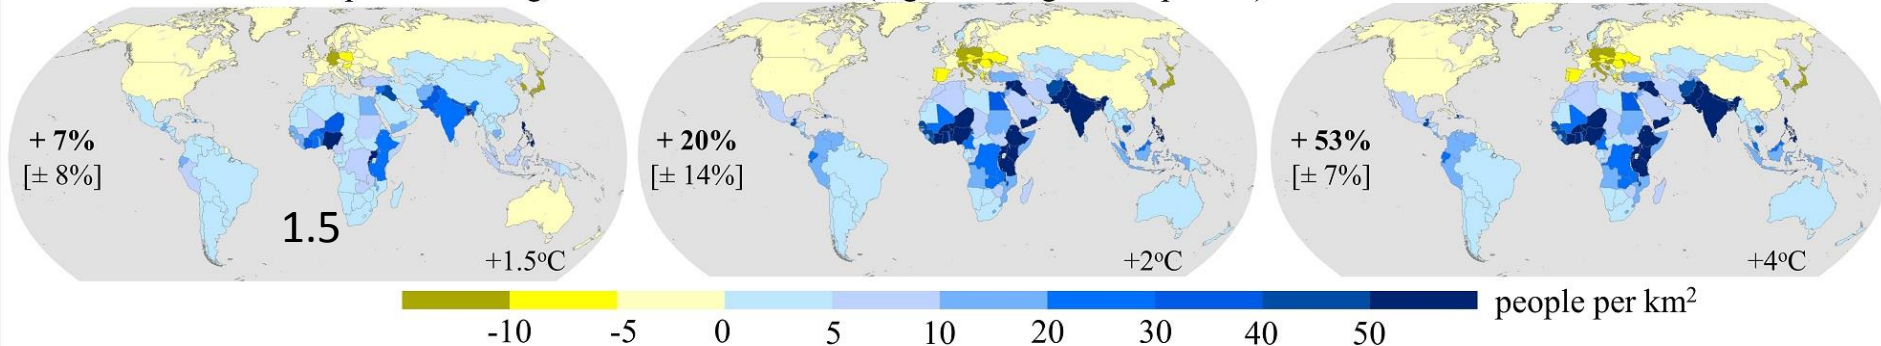

# Population change projections at time of passing global warming levels (ensemble mean)

1.5°C

2°C

4°C

Population change for the SSP3 scenario (high challenge to adaptation) relative to the **baseline**

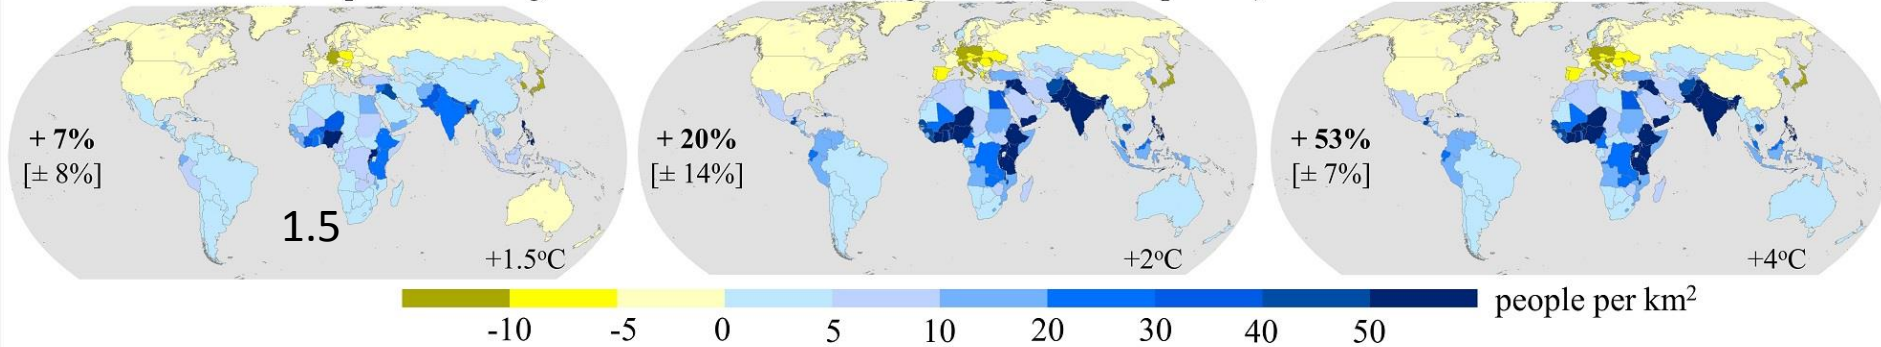

# Population change projections at time of passing global warming levels (ensemble mean)

1.5°C

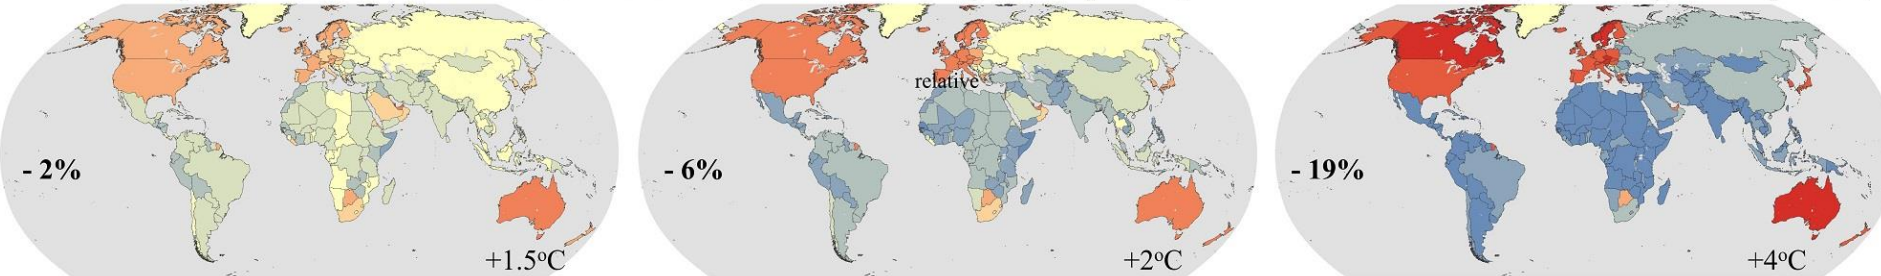

2°C

4°C

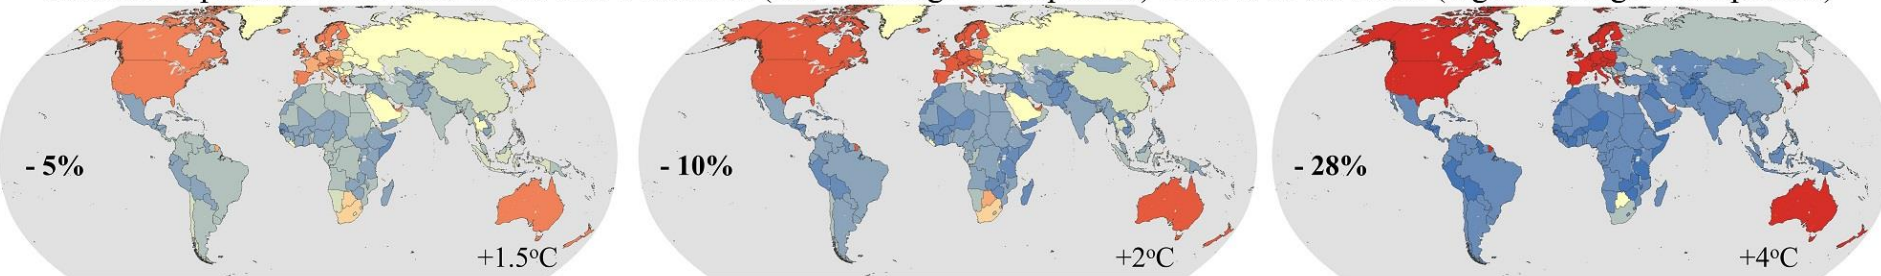

Population change for the **SSP3** scenario (high challenge to adaptation) relative to the **baseline**

Relative Population difference for the **SSP2** scenario (medium challenge to adaptation) relative to the **SSP3** (high challenge to adaptation)

Relative Population difference for the **SSP5** scenario (low challenge to adaptation) relative to the **SSP3** (high challenge to adaptation)

-50% -20% -10% -5% -2% +2% +5% +10% +20% +50%

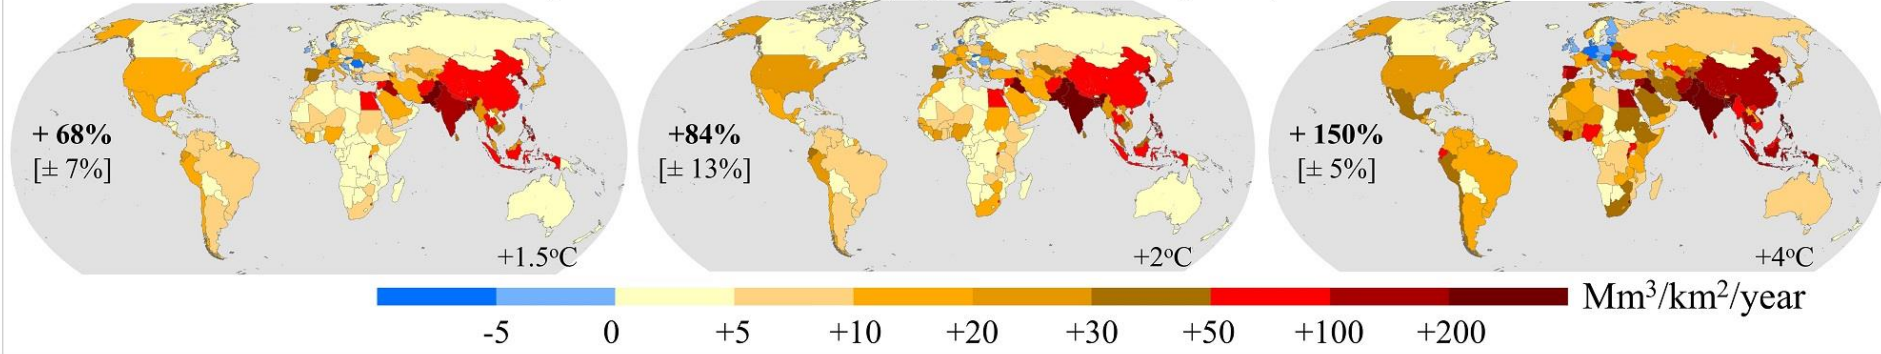

# Water demand projections at time of passing global warming levels (ensemble mean)

1.5°C

2°C

4°C

Water demand change for the SSP3 scenario (high challenge to adaptation) relative to the **baseline**

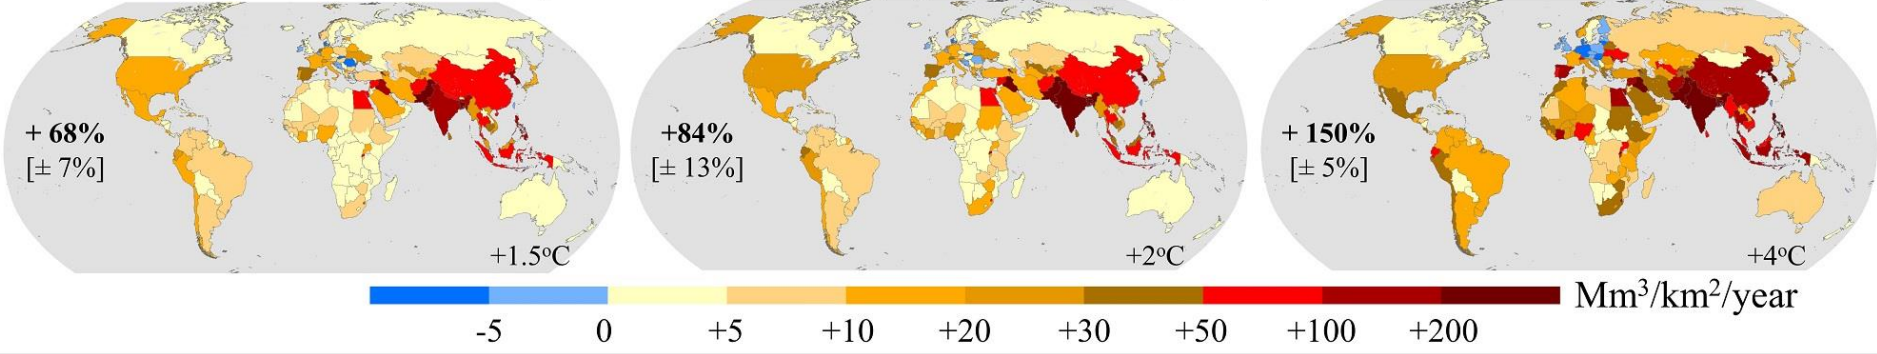

# Water demand projections at time of passing global warming levels (ensemble mean)

1.5°C

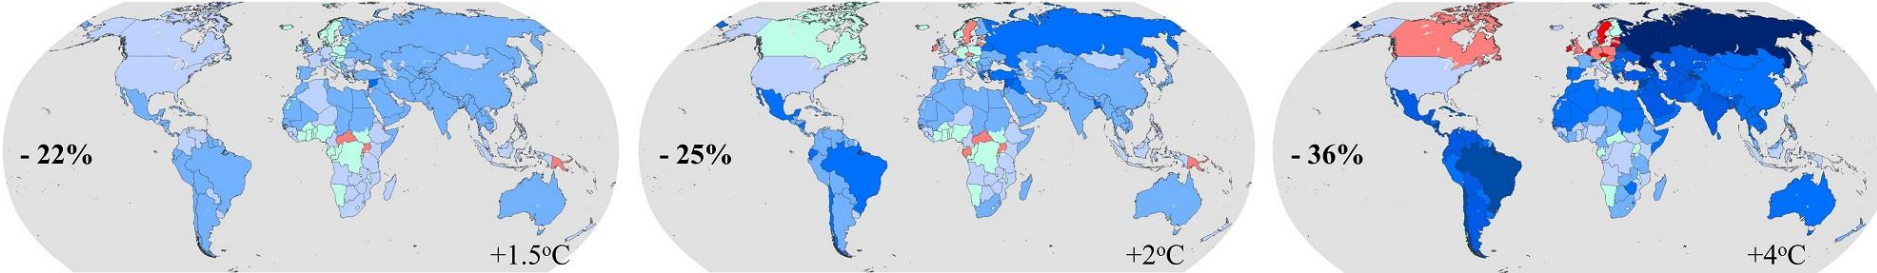

2°C

4°C

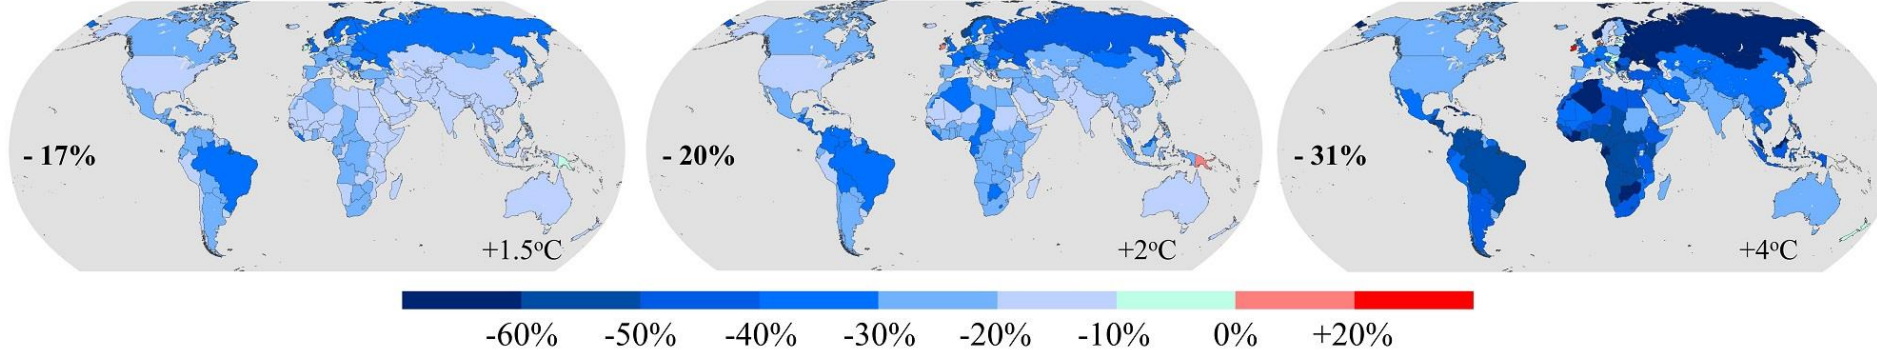

Water demand change for the **SSP3** scenario (high challenge to adaptation) relative to the **baseline**

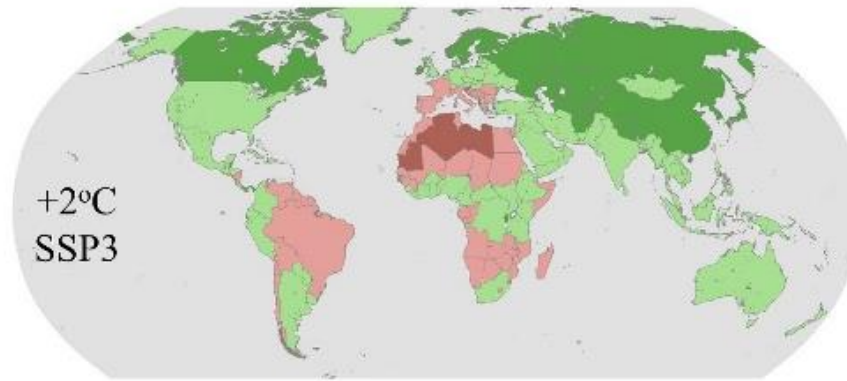

Relative water demand difference for the **SSP2** scenario (medium challenge to adaptation) relative to the **SSP3** (high challenge to adaptation)

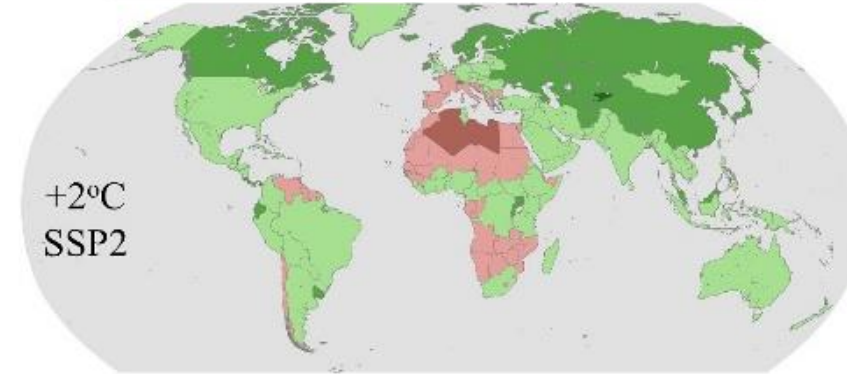

Relative water demand difference for the **SSP5** scenario (low challenge to adaptation) relative to the **SSP3** (high challenge to adaptation)

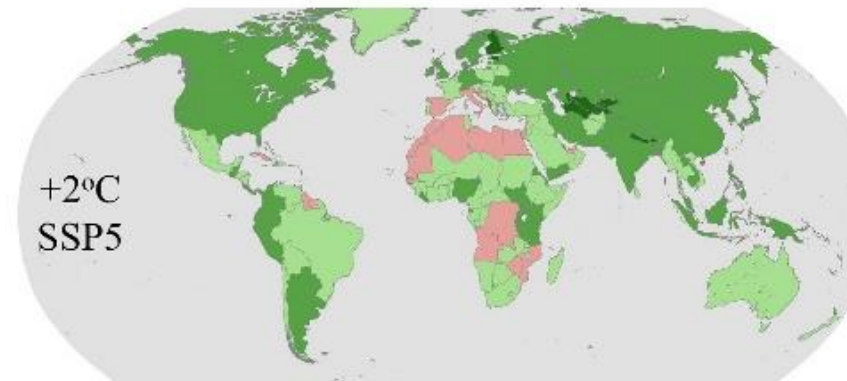

Changes in  
water resource  
vulnerability to  
at 2°C global  
warming  
(ensemble  
mean)

High challenge  
to adaptation

Medium  
challenge to  
adaptation

Low challenge  
to adaptation

Vulnerability change

# Global vulnerability: fraction of land area

- SSP3 High challenges to adaptation
- SSP2 Medium challenges to adaptation
- SSP5 Low challenges to adaptation

# Global vulnerability: population

- SSP3 High challenges to adaptation
- SSP2 Medium challenges to adaptation
- SSP5 Low challenges to adaptation

- At **2°C global warming**, complex geographical pattern of changes in freshwater resources. **Many areas get wetter but some get drier**
- Uncertainty in this depends on sea surface temperature and sea ice patterns, and also on which atmosphere model is used
- Generally **smaller changes at 1.5°C** but not in all basins (may be noise of variability)
- Generally **larger changes at 4°C**
- **Uncertainty increases with global warming**
- Socioeconomic scenario is a first-order effect on human impact
- For scenario with low challenge to adaptation, global water resource vulnerability projected to decrease
- For scenario with **high challenge to adaptation**, global water resource **vulnerability could either increase or decrease** with warming depending on patterns of climate change
